NBER Working Paper No. 11289
April 2005, Revised January 2006
JEL No. F0, O0, Q0

ABSTRACT

This paper investigates the impact of rich-country agricultural support on the poor. Using non-parametric analysis we establish that the majority of poor countries are consistently net importers of food products that are heavily supported by OECD governments. Using a cross-country regression framework we measure the overall impact of agricultural support policies in rich countries on poverty and average incomes in poor countries. We find no support in the cross-country analysis for the claim that OECD policies worsen poverty in developing countries. To better understand what might drive these results, we turn to national employment and household consumption and expenditure surveys from Mexico. There are four important findings from the country case study: (1) the majority of the poorest corn farmers in Mexico report that they never sell any corn, (2) Mexico's own policies (signing NAFTA) have dramatically reduced the Mexican producer price of corn, (3) US corn subsidies have had a limited impact on this price and, (4) domestic policies have largely cushioned Mexican corn farmers from the drop in corn prices. Taken together, the evidence suggests that a reduction in rich-country agricultural support that raises world food prices is likely to hurt the poorest countries but may have little impact at all on the poorest farmers within these countries.

“The rural poor [in Mexico] growing maize for subsistence saw their livelihoods destroyed by a flood of cheap US imports.”

-Oxfam briefing on agricultural subsidies, 2002

“It must be acknowledged that unqualified assertions by many, including the heads of some multilateral institutions, that subsidies and other interventions in agriculture in the OECD countries are hurting the poor countries are not grounded in facts... The claim that the change will bring net gains to the least developed countries as a whole is at best questionable and at worst outright wrong.”

- Economist Arvind Panagariya, 2002

1 Introduction

Rich countries are under increasing pressure from around the world to end support to agriculture. Agricultural subsidies and price supports allow Organization for Economic Cooperation and Development (OECD) countries to sell their agricultural products on world markets at prices that are below the cost of production.¹ Critics claim that these policies inflict harm on poor countries by depressing world commodity prices.^{2 3} Further, they argue that these policies are likely to hurt the poorest residents of the poor countries because poor people are often farmers. Thus, eliminating support for rich country farmers will raise world prices and the incomes of the poor. Our goal in this paper is to evaluate these claims systematically by measuring the impact of OECD agricultural policies on poverty in developing countries.

Because of the diversity both within and among developing countries, the extent to which rich country support policies translate into lower incomes in developing countries is an empirical question. Many least developed countries, especially in Africa, are net importers of food. As net food importers, they may be hurt by higher commodity prices (Panagariya 2002, 2004, Valdes and McCalla 1999). Some countries may import

¹ Transfers to agricultural producers from consumers and taxpayers as a result of income and price support policies equaled \$21,000 per farmer in the United States (US) and \$16,000 per farmer in the European Union (EU) in 1998-2000 (OECD 2001). This is almost one hundred times greater than per capita incomes in the least developed countries.

² Some also argue that these subsidies increase the volatility of commodity prices since support policies that are counter-cyclical with respect to domestic prices or shocks provide incentives for increased production when world prices are relatively low.

³ James D. Wolfensohn, president of the World Bank, has stated that rich countries are “squandering” \$1 billion a day on farm subsidies that hurt farmers in Latin America and Africa. Stanley Fischer, who was the IMF’s deputy managing director in the 1990’s, has said the United States, Europe, and Japan pursue agricultural protection policies that are “scandalous” because of the harm they inflict on poor countries (New York Times, September 30, 2002).

cereals, such as maize and rice, but export other agricultural products such as sugar or cotton. Higher prices for exports and imports will have net effects that are difficult to predict *ex ante*. Even within importing countries, the poorest members of society may be net sellers of food.

We begin our analysis with an investigation into the relationship between income per capita and the value of net cereal, food, and agricultural (food plus non-food) exports for each of the three decades leading up to 2000. We find that – on average - the poorest countries have historically been net importers of cereals and food, the products most heavily supported by the OECD countries, just as they are today. That this pattern has not changed over the past thirty years casts some doubt on the notion that “dumping” turned exporters into importers. We also find that the poorest countries are – on average - net exporters of all agricultural products. However, with the important exception of cotton, the non-food agricultural products are typically not the products supported by the OECD.⁴

What about the poor people in poor countries? To determine whether OECD policy hurts the poorest residents of the poor countries, we use a cross-country regression framework in which the head-count poverty rate (or average income) is the dependent variable⁵. Our innovation is to include as an explanatory variable a measure of rich-country support for the agricultural products produced in the developing country in question. To our knowledge, this is the first use of this strategy to quantify the impacts of rich-country agricultural support policies on poor countries.⁶ Also using this framework, we assess the relative importance of own-country characteristics and policies. We find no

⁴ Panagariya (Financial Times 2004) has recently made a similar point.

⁵ We introduce a new variable into a standard cross-country regression framework previously employed by others including Easterly and Levine (2003), Rodrik, Subramanian and Trebi (2002), and Acemoglu, Johnson, and Robinson (2001), and Frankel and Romer (1999).

⁶ There is some evidence that terms of trade can affect incomes and poverty in developing countries. Sarel (1997) presents evidence that improvements in terms of trade are significantly negatively correlated with changes in income inequality in an OLS regression. He argues that since “policies can rarely affect directly terms of trade dynamics,” the implications of this finding are limited. However, policy changes in the OECD can directly affect the magnitude and nature of agricultural support, which in turn may affect commodity prices and developing countries’ terms of trade. Acemoglu and Ventura (2002) present evidence that terms of trade may be quantitatively important for explaining cross-country income differences using an instrumental variables approach to account for the endogenous relationship between growth and changes in terms of trade.

support in the cross-country analysis for the claim that – on average - OECD policies worsen poverty in developing countries.

To better understand the within-country distributional implications of rich-country agricultural subsidies, we complement our macro work with a case study of Mexican corn farmers using data at the farmer and household level. This case is instructive for several reasons. First, Mexico is often offered as a cautionary example of the impacts of agricultural trade liberalization on rural poverty. Second, the case of Mexico raises a number of issues, such as the importance of domestic policy, which can help to inform our cross-country analysis. Finally, we choose Mexico because rich, nationally representative and previously unexploited data sets are available.⁷

Evidence from Mexico confirms the importance of domestic policies relative to international policies that affect commodity border prices, and highlights the importance of distributional issues masked by the cross-country analysis. In the mid-1990s the Mexican government initiated the liberalization of the corn sector in Mexico. As anticipated, this liberalization led to a sharp decrease in the producer price of corn and an increase in Mexican corn imports from the US. Because this liberalization took place in the context of US corn subsidies that lower border prices, the US is sometimes held responsible for the price decline and increased poverty among Mexican corn farmers. Contrary to this popular view, our evidence suggests that US corn subsidies have had a limited impact on the border price of corn. In addition, because the majority of the poorest corn farmers do not sell corn in the market, their incomes were not directly affected by the decline in the producer price of corn. By contrast, a majority of the medium and large corn farmers do participate in the market. Medium-sized corn farmers experienced a sharp decline in real income while the income of the largest corn farmers actually increased. Transfer payments to all corn farmers – also part of the corn market “liberalization” - increased but were structured so that benefits went disproportionately to the rich farmers.

⁷ Our data on Mexico come from INEGI (the Mexican Statistical Agency) and are drawn from two different surveys, the *Encuesta Nacional de Empleo* (ENE), an individual-level national employment survey, including a rich agricultural supplement, and the *Encuesta Nacional de Ingresos y Gastos de los Hogares* (ENIGH), a household-level income and expenditure survey. Both surveys were conducted both pre and post NAFTA though not always for the same years.

Our results stand in stark contrast with the large body of literature that has been devoted to examining the *potential* impact of agricultural trade liberalization on developing countries using computable general equilibrium (CGE) models.⁸ While the magnitudes of CGE estimates vary, agricultural trade liberalization is typically predicted to increase world commodity prices to the *overall* benefit of developing countries. For example, Beghin et al. (2002) estimate that the removal of all agricultural subsidies and trade barriers could increase rural value added in low- and middle-income countries by \$60 billion per year, which, as they note, exceeds most targets for development assistance by some 20 percent. Probably the most important reason for the differences in results is that other studies have not focused explicitly on poverty but rather on developing countries as a whole. Additionally, as pointed out by Panagariya (Financial Times 2004), many studies combine liberalization by developing countries with liberalization by developed countries when estimating welfare impacts. We focus solely on the impacts of rich country policies on poor countries and the poor residents of these countries.

In interpreting our results, a few caveats are in order. First, our measure of OECD policy is effectively the production-weighted average implicit export subsidy faced by each country in our sample. A variety of other OECD actions such as support for minor crops, import tariffs on products not produced domestically (e.g., coffee), phytosanitary regulations, and discretionary protection applied when imports rise may also be important for developing countries but are beyond the scope of this paper. Second, our measure of OECD policy does not include cotton, a key non-food product that is heavily subsidized by the US in a way that harms some very poor countries. Cotton is not included because the OECD calculates support only for the major commodities that make up the first 70 percent of the total value of agricultural production. However, in our view, the inclusion of cotton is unlikely to change our overall findings because it is only exported by a handful of the poorest countries and makes up a relatively small share of these countries' total agricultural production. Third, while we find that *on average* OECD support does not increase poverty and that *the majority* of poor Mexican corn farmers do not

⁸ See for example, OECD 2002, ERS/USDA 2002, Trueblood and Shapouri 1999, Hoekman, Ng, and Olarreaga 2002, Beghin, Roland-Holst, and van der Mensbrugge 2002. Note that some CGE-based studies of the Uruguay Round agreement found results consistent with the focus of this paper, such as Hertel, Masters and Elbehri (1998).

participate in the market, it may still be the case that many poor people are made poorer by these policies. Roughly sixty percent of the poorest Mexican corn farmers do not participate in the market. This means that forty percent of the poorest corn farmers do participate in the market. For these people, the conclusions about the impacts of depressed corn prices are different. Such nuances help us to understand why different groups may have very different perspectives on these issues.

The remainder of this paper is organized as follows: Section 2 establishes the relationships between net exporter status and income for developing countries over time and in the cross-section. Section 3 describes the data and estimation strategy used in the cross-country analysis and presents these results. Section 4 presents an analysis of the impact of a reduction in the price of corn on Mexico's corn farmers. Section 5 concludes.

2. *Are the Poorest Countries Hurt by OECD Support for Agriculture?*

We begin with an investigation into the relationship between income per capita (measured in constant 1985 dollars at PPP exchange rates and collected from the Penn World Tables version 6.1) and the value of net cereal, net food, and net agricultural exports including non-food products as a share of GDP (measured at current prices). This can be thought of as the fraction of current income earned from the sale of these products or spent to purchase these products. Because there is time-series data on agricultural imports and exports, as well as income, it is possible to track the behavior of the cohort of developing countries over time.⁹

We identify the countries that may have been most affected historically by OECD agricultural policy as those that have spent (earned) the greatest fraction of income on imports (exports) of supported products. We are particularly interested in comparing how cereal importers differ from food or non-food agricultural exporters because cereals prices are depressed by OECD agricultural support policies, while the prices of most other food products (with the important exceptions of dairy and sugar) and non-food

⁹ Other authors have also presented data to highlight the diverse agricultural trade profile of developing countries (Valdes and McCalla 1999, Panagariya 2002, 2004), but have emphasized cross-sectional patterns only. This snapshot of countries' trade positions may obscure long-run patterns in the data.

products (with the important exception of cotton) are largely unaffected by OECD support.

Figures 1, 2, and 3, present data on income earned from agricultural exports in three different ways. First, we use data from the FAO to calculate the value of annual net cereal exports as a percentage of GDP for a sample of 99 developing countries¹⁰ and take the average value of this number for the period 1970-1979, 1980-1989, and 1990-2000.¹¹ We show the cross-sectional income profile for these three time periods in Figure 1 by using a locally-weighted regression of decadal average cereal export share on the decadal average of the log of income per capita (bandwidth = 0.8). We run the same regressions for food export share and present those results in Figure 2. Figure 3 shows the regressions for agricultural export shares (including non-food products such as green coffee and fibers).

Figure 1 shows that, in each decade, the poorest countries spend the largest fraction of their incomes on cereal imports, suggesting that they may experience net benefits as a result of depressed cereal prices. In fact, so few developing countries are net cereal exporters in any decade that the predicted net cereal export share is negative even at the highest income levels observed in the data.¹²

Since 1970 the poorest countries have also experienced the smallest reduction in net expenditures on cereal exports as a share of GDP. To trace the average cereal export share of a given country experiencing economic growth, points should not be connected within years, but across the regression lines, linking up the experience and behavior of a like country in the following decade. Thus, the fact that the regression lines are very close to each other at the lowest levels of income suggests that net export increases experienced at higher income levels largely bypassed the poorest countries in the post-colonial era.

These data suggest that depressed prices for food products may hurt middle-income countries but help the poorest and richest developing countries. As shown in

¹⁰ The sample includes three transition economies: Poland, Romania, and Hungary.

¹¹ The FAO definition of cereals include wheat, paddy rice, barley, maize, pop corn, rye, oats, millet, sorghum, buckwheat, quinoa, fonio, triticale, canary seed, and mixed grains.

¹² Among countries for which data is available, Thailand, Argentina, Nepal, Zimbabwe, South Africa, Uruguay, Pakistan, Kenya and Guyana had positive average net export earnings from cereals in the 1970s. This list expanded to include Vietnam, in the 1980s, but lost Nepal and Kenya. In the 1990s, Guyana, Argentina, Thailand, Vietnam, Hungary, Paraguay, India, and Pakistan had positive net export earnings from cereals.

Figure 2, and unlike in the case of cereals alone, among non-OECD countries only middle-income countries earn income from food exports. The cross-sectional relationship between net earnings from all food exports as a share of GDP is non-monotonic. This production category includes non-cereal products that receive high levels of support in the OECD, including sugar, beef, and dairy products, as well as unsubsidized products such as cocoa and most fruits and vegetables.

The cross-sectional relationship between food export earnings share and income appears to be flattening over time. In the 1970s, a country with an income of \$1,100 is predicted to have positive net food exports. A country with this level of income in the 1980s or 1990s is predicted to be a net food importer. The trend in this data appears to be towards zero net earnings from food exports. Though not shown here, this impression is even stronger when the sample size is enlarged to include 21 high-income OECD member countries.

Poor countries are most likely to be net exporters of agricultural products in total, as shown in Figure 3.¹³ We run the same regressions to create this figure, but consider all agricultural products, including fibers, industrial seeds, green coffee, and tobacco. In this case we find a downward-sloping relationship between net export earnings and income. Relatively well-off developing countries import agricultural products as a whole. This suggests that depressed prices for non-food agricultural products like cotton are particularly damaging to the poorest countries.

Figures 1, 2, and 3 together provide evidence that many poor countries import cereals but export agricultural products as a whole, and have been in this position throughout the post-colonial era. As we show in Table 1, which ranks countries by current income per capita and summarizes the data from the latest decade that is presented graphically in Figures 1 through 3, many poor countries, and even many middle-income countries, that export food products import cereals, particularly in the 1990s. Depressed commodity prices as a result of domestic support for agriculture in the

¹³ In particular, this category of products includes cotton, an important export crop for several West African countries as well as Brazil, China, and India. Cotton is excluded from our regression analysis because, although production data is available from the FAO, support levels are not calculated for this crop. This support is certainly not trivial; about \$2.3 million was provided as assistance to US cotton growers in 2001-02 (International Cotton Advisory Committee 2002). The OECD calculates support only for the major commodities that make up the first 70 percent of the total value of agricultural production.

OECD could lower the value of both imported products and exported products for these countries. While it is true that a majority of poor countries are net exporters of agricultural products today (see Table 1), among the non-food products cotton stands out as the only non-food commodity whose price is likely to be significantly depressed by OECD agricultural support.

Of course the experience of developing countries is diverse and, because they are regressions, Figures 1 through 3 obscure differences in countries' experiences at any income level. However, these results suggest that it is unlikely that broad agricultural liberalization, which is likely to result in higher world prices for cereals as well as dairy, sugar, and cotton, will benefit the majority of the poorest countries.

Country-level average values of net cereals or food exports tell us little about what happens to the poor within a country. Even in countries that are net importers of food, the poor may be net exporters of food. Thus, a poor country might be hurt by higher food prices while the poor within that country benefit from higher food prices. The remainder of the paper is devoted to this issue.

3. Does OECD Support Hurt the Poorest People in Poor Countries?

Even if the poorest countries are net importers of products protected and subsidized by OECD governments, it is possible that the poorest people within these countries are net sellers of these cheap imports. If this were the case, then OECD support that benefits the country as a whole could increase poverty in that same country. In fact, this is a common assumption based on the observation that poverty tends to be concentrated in rural areas. We begin this section by describing our approach to testing this hypothesis in a cross-country regression framework. This is followed by a description of our methodology for obtaining country-specific measures of OECD support and a description of our data. We conclude with a presentation of results.

3.1 Empirical Strategy

To test the claim that OECD support for agriculture hurts the poor, we begin by estimating the following equation:

$$(1) \quad \log HP_{it} = \alpha_i + \gamma \log OECDPOLICY_{it} + \varepsilon_{it},$$

where HP is the headcount poverty rate for country i at time t based on the \$1 a day poverty line, α_i is a country fixed effect, and $OECDPOLICY$ is a country-specific measure of OECD support that varies over time and whose construction we discuss in the next sub-section. This simple specification allows us to preserve the largest number of observations for which data on poverty and OECD support is available. In this specification, γ represents the elasticity of poverty with respect to OECD support. Critics of OECD agricultural policy would expect γ to be positive and significant. To this basic equation, we add additional controls for comparability with previous work and to test the notion that own country policies are more important than OECD support as determinants of poverty.

One potential problem with this specification has to do with the endogeneity between OECD support and world commodity prices. OECD support is a function of commodity price fluctuations and domestic political considerations. Commodity price fluctuations can in turn be affected by OECD policy. Thus, in principal, we need to take care in the interpretation of γ . In other words, we could mistakenly attribute to OECD policy changes in poverty that are being driven purely by changes in commodity prices. Practically, this is a moot issue since we find no significant relationship between OECD policy and poverty.

A second problem with this approach is the limited availability of the intersection of poverty data and data on OECD support to agriculture. Because these data are sparse and since there is a strong association between average income and poverty reduction, we also consider the impact of OECD support on average income in developing countries by estimating the following equation:

$$(2) \quad \log y_{it} = \delta_i + \beta \log OECDPOLICY_{it} + \sigma_{it}$$

The only difference between equation (2) and equation (1) is that in equation (2) we now insert average income per capita as the dependent variable.

One advantage to estimating equations (1) and (2) is that the time-invariant factors that affect poverty and income such as institutions, geography, and structural measures of integration are subsumed in the country fixed effects. We also control for time-variant global trends that may affect incomes, such as global weather shocks and energy prices using time fixed effects.

3.2 Data

Our main innovation is in constructing *OECDPOLICY*, a country- and year-specific measure of OECD support to agriculture. Therefore, we devote the majority of this section to describing both how the OECD computes commodity- and year-specific measures of distortionary support and how we aggregate these data into variables that can be included in the regression analysis. We then briefly describe the other variables used in our analysis.

Since 1987 the OECD has tracked support, by commodity, for agriculture in member countries. The United States Department of Agriculture (USDA) has calculated support by commodity and country for the period 1982-1990. In order to use these data to develop the variable *OECDPOLICY*, we need to select a measure of domestic support and identify a means of aggregating support measures across commodities to develop a country-specific measure of other countries' agricultural policies.

The Producer Support Estimate (PSE) is the most commonly used measure of domestic support for agriculture. The PSE measures the annual monetary value, at the farm gate, of gross transfers from consumers and taxpayers to agricultural producers arising from policy measures to support agriculture.¹⁴ The PSE for a commodity is usually presented as a fraction of the value of total gross farm receipts for the commodity. This is referred to as the "percent PSE" and measures the portion of farmer receipts attributable to policy.¹⁵

¹⁴ The PSE includes domestic subsidies to agriculture, barriers to market access, and export subsidies. It does not include food aid (OECD 2001). The PSE includes implicit payments, such as those that arise from commodity-specific price gaps created by trade barriers, but excludes gaps between domestic and border prices that may arise because of transportation costs, quality differences, or marketing margins.

¹⁵ The percent PSE has several potential shortcomings when considering how it might be used in econometric analysis (Masters 1993, Wise 2004). It is possible that total support for agricultural producers as measured by the PSE could be increased by policy changes, while the distortionary effects of support are reduced by changes in the policy mix used to support agriculture (e.g., if export subsidies were replaced

An alternative definition of trade-distorting support is the producer nominal protection coefficient (NPC), which is defined as the ratio between the average price received by producers (at farm gate) and the border price (net of transportation costs and marketing margins). This is conceptually equivalent to the implicit export subsidy necessary to export the observed quantity produced. An NPC equal to one implies that producers receive border prices for their output after adjusting for transportation costs and thus do not receive production-distorting signals from agricultural support policies. The NPC is calculated on a commodity-by-commodity basis for the OECD as a whole by taking a production-weighted average of producer prices and a common border price.

A third measure of support calculated by the OECD is the producer nominal assistance coefficient (NAC) which is defined as the ratio of the value of total gross farm receipts, including support, and production valued at world market prices, without support. The NAC is related to the PSE, but calculates support independent of exchange rate effects. When the NAC is equal to one, receipts are entirely derived from the market.

All three measures of support for agriculture are highly correlated within countries, and correlated across countries, both in aggregate and by commodity. In the main regression specifications discussed in this paper, we measure support for agriculture in the OECD by commodity using the NPC. However, our results are robust to alternative measures of support. Figure 4 reports the NPC by commodity for the OECD for the periods 1986-88 and 2000-02. Milk, sugar, and rice receive the highest levels of production-distorting support.

In order to estimate equations (1) and (2), we must identify which OECD support policies are relevant to country i in period t by matching support policies to countries in a way that reflects the relative importance of support by commodity for each country. That is, for a non-OECD country i , we must identify a set of weights to use to combine measures of the NPC for the following products: wheat, maize, rice, other grains, oilseeds, sugar, milk, beef, sheepmeat, wool, pigmeat, poultry, and eggs. These are the products for which the NPC is calculated by the OECD and USDA. We must also

with decoupled income or production support). This is because the PSE is made up of several categories of transfers that have differing impacts on production, consumption, and trade. Thus, the most common measure of support may not be the most appropriate for our analysis; we do not expect policies that do not affect trade to impact developing countries.

appropriately account for the fact that countries produce other agricultural products for which the NPC is equal to one.

We create the variable *OECDPOLICY* as a weighted average of support provided by rich country governments to growers of these products (or similar commodities that are likely substitutes for it) in each year for the period 1982-2000, where weights are defined by the share of each product in the developing country's agricultural output in 1970.¹⁶ This approach should avoid the problem that current production choices are partly determined by current subsidy levels. In addition, some African countries have severely discriminated against agriculture in the past; we want to consider their potential exports (as measured by their sectoral structure in 1970) rather than their actual exports or production. For commodities that have a calculated NPC we use FAO data on 1970 total production of the following products: wheat, maize, rice, other grains (calculated as total cereals less wheat, maize, and rice), oilseeds (including cake and meal), sugar (refined, cane, and beet), milk (condensed, dry, and fresh), beef and veal, sheepmeat (fresh), wool (greasy), pigmeat, poultrymeat, and eggs. For vegetables and melons, all roots and tubers, all fibers, coffee, cocoa, and all fruits, we set the NPC equal to one.¹⁷

African countries, which have a relatively large fraction of historical agricultural production in roots and tubers and coffee and cocoa tend to have low levels of *OECDPOLICY*. Small countries that import essentially all their food needs also have low values of *OECDPOLICY*. Conversely, rice producers have high values of *OECDPOLICY*. Grain and oilseed exporters, such as Brazil, tend to have values of *OECDPOLICY* that fall in the middle of the distribution.

We note in Table 1 the countries included in our regression analysis – a subset of the countries included in Figures 1 through 3. Our largest sample includes 75 developing

¹⁶ Ideally, this approach would use developing country agricultural sectoral composition in 1930-- before the architecture of modern OECD farm policy was put in place. Data from this period may be of poor quality however, to the extent that it exists.

¹⁷ By assuming an NPC of one for fibers we underestimate the value of *OECDPOLICY* for cotton producers. Even excluding cotton, bound tariffs for these products are not uniformly equal to zero in developed countries. Thus, our approach underestimates *OECDPOLICY*. However, tariffs for these products are much lower than bound tariffs for so-called program crops and those commodities for which the OECD calculates an NPC. There are also relatively few mega-tariffs for these products. For example, WTO bound tariffs reported by the US include 19 tariffs of 100 percent or higher. Only six of these are for products for which we assume an NPC of one and these are minor products in the nuts and tobacco commodity group.

countries for the period 1982-2001. We also identify the countries that are members of the Cairns Group, currently considered to be among the most competitive agricultural exporters. Far more countries in our sample are net food and cereal importers than exporters, which is consistent with our discussion in section 2 of the experience of a larger sample of developing countries. Notably however, the Cairns Group countries are not all historical exporters; Bolivia, Chile, and Indonesia were net importers of food and cereals in the 1970s, for example.

Our data on income per capita, measured in 1996 purchasing power parity (PPP) dollars come from the Penn World Tables, version 6.1. To control for global weather shocks that impact commodity prices we use a common measure of the El Nino-Southern Oscillation (ENSO) severity called the Southern Oscillation Index (SOI) anomaly.¹⁸ Recent research has shown that ENSO severity can explain as much as 20 percent of annual commodity price variation (Brunner 2002). There is also a positive correlation between ENSO, as measured by the SOI anomaly, and GDP growth. Thus, we expect the coefficient on this variable to be positive.

Table 2 reports summary statistics for all of the variables used to estimate equations (1) and (2). We report these statistics for the entire sample and then separately for the Cairns Group and for historical food importers.¹⁹ We define countries that were food and cereal exporters or importers based on data for the 1970s, the decade prior to our analysis. Food-importing countries have higher average incomes than the Cairns Group food exporters because several well-off island countries (e.g., Hong Kong and Singapore) are food importers. However, the variance of incomes in the Cairns Group is significantly lower among food importers. None of the poorest countries in the sample are in this group. These patterns are stable across the two decades that we consider.

Because our specification includes country dummies, our measures of a country's own policies were chosen to reflect trade and macro policies that vary significantly over time within countries. Therefore, the variables we use to control for "own country policies" are trade share (exports plus imports divided by GDP) and inflation. Table 2

¹⁸The SOI anomaly measures deviations between air pressure differentials in the South Pacific and historical averages. For each year, we take the average of the SOI anomaly as measured in January and June. This data is available from the NOAA.

shows that the Cairns Group of countries are richer than the rest of the countries in the sample. They also have a significantly smaller share of the population below the poverty line. The trade share of GDP is actually lower for the Cairns Group which is likely to be explained by the differences in GDP. *OECDPOLICY* is slightly higher for the Cairns Group implying that these countries are slightly more vulnerable to OECD subsidies. The rate of inflation in the Cairns Group is nearly double that in the rest of the sample. This is because 9 of the 14 Cairns Group countries are in Latin America where inflation has been notoriously problematic

3.3 Results

Tables 3 and 4 present the results of estimating equations (1) and (2) respectively. In both tables, the estimates are separated into three panels. Panel A presents results for the entire sample. There is good reason to believe that the coefficient on *OECDPOLICY* will vary across countries. Specifically, the effect of changes in commodity prices on poverty (income) is likely to depend on whether a country is a net importer or net exporter of the product in question. Therefore, in panels B and C we relax the assumption of a constant elasticity of poverty (income) with respect to OECD policy. In Panel B we estimate equations (1) and (2) for members of the Cairns Group and in Panel C we estimate these equations for countries that are historical net food importers.

We begin by looking at the results of the estimation of equation (1) for the entire sample. The regressions in columns 1 and 2 report the simple correlation between *OECDPOLICY* and poverty. In column (1) we control only for country fixed effects – in column (2) we add time fixed effects. In columns (3) through (6) we add a measure of average income and a measure of weather fluctuations and in columns (5) and (6) we add two measures of domestic policy – trade as a share of GDP and the log of inflation. The only robust result across specifications is the relationship between average income and poverty documented by Besley and Burgess (2003).

Imposing the assumption of a constant elasticity across countries is one reason that we might not find any relationship between OECD policy and poverty. We check

¹⁹ In Table 2 and in the regression analysis, Bolivia, Chile, and Indonesia are included only in the Cairns Group sample. They are not included in the historical food importers sample.

this by estimating equation (1) separately in panel B for the Cairns group, the group of countries pushing for agricultural liberalization and most expected to benefit from agricultural liberalization. The results in Panel B are not much different from those in Panel A. We turn next to the group of countries expected to lose as a result of higher food prices, historical food importers. Once again, the coefficient on OECD policy is insignificantly different from zero. For this sub-sample of countries, reducing inflation is associated with poverty reduction.

Why do we find no relationship between OECD policy and poverty? The most obvious explanation is the lack of data. Our entire sample consists of a little over 200 observations and for most countries because the poverty data is only available for two or three years. We can partially address this issue by redefining our dependent variable to be average income per capita. To obtain the link between OECD policy and poverty, we can then rely on the link between average income and poverty documented by Besley and Burgess (2003) and evident in our Table 3.

Table 4 reports the results of estimating equation (2). In Panel A we report estimates for the whole sample. Like in Table 3, there is no evidence of any robust relationship between OECD policy and average income per capita in developing countries. We do find that good weather has a small effect on average income (as previously documented by Brunner 2002) In Panel B of Table 4 we present the same sequence of regression results for the smaller sample of Cairns Group countries. Recall that some of these countries were actually food importers in the 1970s. These are the countries for which we predict a negative correlation between *OECDPOLICY* and income per capita. Again, the sign on *OECDPOLICY* is opposite to what we'd predict but the coefficient is so imprecisely measured that we cannot distinguish it from zero. We examine the impact of *OECDPOLICY* on historical food importers in Panel C. This is the group for which we predicted a positive relationship between *OECDPOLICY* and income per capita. The sign on *OECDPOLICY* is as predicted but again the result is insignificantly distinguishable from zero in all but one instance. There is a dichotomy between the Cairns group sample and the historical food importers in that trade share is positively correlated with income for the Cairns group but has no relationship to income for the historical food importers. By contrast, inflation is negatively correlated with

income for historical food importers and does not appear to matter for the Cairns group countries.

3.4 Discussion

In summary, we find no evidence in our regression analysis that – *on average* – OECD policies help or hurt the poor. Several caveats are in order. First, for each country, we are looking at a package of policies that includes all of the products produced by the developing country. It is possible for a country to be a net exporter of one commodity and a net importer of a second commodity both subsidized by the OECD countries. The effects of a price decline would have different effects in the different sectors and we are unable to capture this in our current framework, which focuses on aggregate effects. Second, looking at average income might be misleading if – as many of the advocates for the poor suggest – the poor are the net sellers of these products and the relatively well off are the net consumers of these same products. In this case, OECD policy, by depressing commodity prices, could make the poor worse off and the rich better off leaving average income unchanged. We would capture this in our poverty regressions but, as we mentioned, these data are sparse. Finally, the poverty data are likely to include government transfers in some cases and not in others. This is problematic because it makes it difficult to isolate the impact of OECD policy on poverty.

4 Do US Corn Subsidies Hurt Poor Mexican Corn Farmers?

In this section of the paper, we evaluate the claim that US support to corn farmers – by depressing Mexican producer prices – has been largely responsible for the increase in rural poverty in Mexico.²⁰ We begin by documenting the decline in the Mexican producer price of corn. Next we consider the reasons for this decline – was it primarily Mexican policy or US policy? We also consider the possibility that the majority of corn farmers living far from the border in states like Chiapas are sheltered from

²⁰ For example, in a recent policy brief Oxfam (2003) argues that NAFTA has been responsible for a surge in US corn exports to Mexico and the associated decline in the real producer price of corn. Moreover, the brief argues that Mexican corn farmers are at a distinct disadvantage vis a vis US corn farmers because of the huge subsidies paid out by the US government. The result of this flood of cheap US imports has been an increase in poverty of the 15 million Mexicans who depend on corn as a source of income.

changes in the world price of corn. Finally, we analyze the impact of the decline in producer prices on Mexican corn farmers and their families.

Mexican corn is an ideal case study for our purposes for a number of reasons. Mexico is an importer of corn and has been for several decades. Corn is also a product heavily subsidized by the OECD countries and in particular the US, a major trading partner of Mexico. We have national employment surveys and household data that includes detailed information on corn expenditures and sources of income including income received in the form of government transfers. These data are available for the period 1990 to 2000 – the period over which the real Mexican producer price of corn declined by more than fifty percent. Thus, we can learn a great deal about the impact of depressed commodity prices on the poor by studying the case of Mexico. We also have time series data on regional producer prices and reference prices that allow us to explore the determinants of the decline in producer prices including the extent to which producer prices move with world prices. We rely on existing work that examines the link between world corn prices and US corn subsidies to estimate the relative importance of US corn subsidies as a determinant of the Mexican producer price of corn.

As we discussed extensively in the first half of this paper, the impact of a price decline on poverty depends on whether the poor are net buyers or net sellers of the commodity in question. This is as true for households as it is for countries, but has largely been ignored in discussions of the impact of corn trade liberalization on Mexico (see, for example Nadal 2001 and World Bank 2004).²¹

Using nationally representative survey data for the years 1991 through 2000, we study the *actual* impact of a reduction in the price of corn on poverty among corn farmers in Mexico. Like De Janvry, Sadoulet and de Anda (1995), we are interested in identifying net sellers of corn. Because detailed data on income and expenditure are not recorded in

²¹ Two papers written prior to the implementation of NAFTA do consider the possibility that poor Mexican corn farmers might actually be net consumers of corn. Using household survey data from 1990 for three states in Mexico, de Janvry, Sadoulet and de Anda (1995) find that the majority of small and medium sized corn producers do not produce for the market. They *predict* therefore that most corn farmers' income will not be directly affected by the decline in the price of corn associated with NAFTA, while a significant share will benefit as consumers. Using a general equilibrium framework, Levy and Van Wijnbergen (1995) quantify the impact on household welfare, labor and land markets of liberalizing the Mexican corn sector. This paper makes the important point that even subsistence farmers who do not sell corn are likely to sell labor. Thus, to the extent that the drop in corn prices reduces rural wages, subsistence farmers are likely to be hurt by the liberalization of the corn sector.

the same survey, making it difficult to identify households that are net sellers, we use information from the National Employment Survey to document over time by measures of living standard (size of land holdings) the share of corn farmers who report that they sell corn and the changes in these farmers' income. This exercise allows us to determine the share of the poorest corn farmers whose income has been directly affected by changes in the price of corn because they sell corn.

Of course, even if individual farmer's earnings from corn farming have fallen, it could be that total household expenditures on corn products have fallen by even more, in which case the household to which the corn farmer belongs would be a net beneficiary of the reduction in the price of corn. Since the National Employment Survey only tracks income from the respondents' primary job, we use household survey data to document, by measures of living standard, changes in income and expenditure on corn products of families with family members who report that their primary or secondary source of income is corn farming. While the household survey does not specifically ask for the amount of income derived from corn farming, it does ask whether the household members' primary source of income is corn farming. In addition, the survey asks each individual member of the household whether their income is derived from labor (work income), from business (profit income), from remittances both domestic and international (income from remittances), from government programs (income from transfers) or other sources such as rental income (other income). For those households who report that their primary source of income is corn farming, the work and profit share of income reported is derived primarily from corn farming. Thus, a comparison between changes in income and changes in expenditure on corn products allows us to determine whether households that rely on corn farming as a primary or secondary source of income (and in particular, the poorest corn farmers) have on net benefited from a reduction in the price of corn.²²

To determine the relative impact of domestic policy and international policy on the producer price of corn, we examine extent to which US subsidies have depressed Mexican producer prices and we study the pattern of corn prices across time and across states. Our primary goal here is to determine the reason for the dramatic decline in the

²² One complication which we do not address is the fact that corn is purchased in many different forms. Thus, it is harder to argue that the expenditure patterns are attributable solely or even primarily to NAFTA.

producer price of corn over the period 1986-2002. First, we consider the impact of domestic policy (“my policies”) on the producer price by comparing Mexican producer prices to border prices pre- and post- 1994, the year the North American Free Trade Agreement (NAFTA) between Canada, Mexico and the US was signed. We focus on NAFTA because it marks the beginning of the liberalization of the corn market. Importantly, NAFTA encompasses both policies designed to align Mexican producer prices with world prices (such as tariff liberalization) and domestic policies designed to soften the negative consequences of this liberalization. We extend this analysis to a comparison of prices at the state level to determine whether – as some claim - states furthest from the border have been shielded from trade liberalization. To obtain an estimate of the impact of US subsidies on border prices, or how much higher border price would be in the absence of US subsidies (“your policies”), we rely on a recent survey of this issue by Wise (2004).

One important caveat is in order. Our data do not track the same households over time and therefore, we are unable to document what has happened to the income of farmers and households who relied heavily on corn farming prior to liberalization and who then switched out of corn farming into some other activity. To understand whether in fact our results suffer from a serious selection bias, we examine farmer (and corn-farming household) characteristics over time to determine whether these have changed substantially. In future work, we will use regression analysis and correct for selection bias.

The remainder of this case study is organized as follows. We first describe the policy environment in Mexico. Next we assess the relative importance of “my policies” (NAFTA) or “your policies” (US corn subsidies) in determining the Mexican producer price of corn. We then consider the impact of these policies on poverty among Mexican corn farmers. We conclude with outstanding issues and directions for future research.

4.1 The Policy Environment in Mexico

This section of the paper is devoted to describing the package of policies known as NAFTA. NAFTA – the critics claim – has exposed poor Mexican corn farmers to cheap US imports. However, it is important to remember that NAFTA included several

policy reforms beyond the removal of tariffs. It is also worth noting that NAFTA was freely agreed to by the Mexican government and thus, should be counted among “my policies” in the parlance of this paper.

Since the implementation of NAFTA, tariffs on imported corn have been dramatically reduced. The Mexican over-quota bound tariff on corn has been reduced from 206.4 percent to 72.6 percent and the tariff-rate quota (TRQ) has increased from 2.5 million metric tons to 3.36 million metric tons. At the same time, Mexico has converted its import licensing system to a transitional tariff-rate quota that will remain effective until 2008 with a three percent annual increase in quantity. Over the first six years of the agreement, an aggregate 24 percent of the tariff was eliminated. The remainder will be phased out by 2008.

NAFTA included several policy reforms, beyond the removal of tariffs that affected corn farmers. The reforms in the agricultural sector that most directly affected corn farmers are the removal of price supports and the implementation of direct income transfers. Other reforms that would have had an impact on corn farmers are an extension program aimed at raising productivity, changes in credit and land reform. We discuss each of these below, drawing on a recent evaluation of the effect of NAFTA on Mexico’s agricultural sector (Yunez-Naude and Paredes 2002).

According to Yunez-Naude and Paredes (2002), it is widely agreed that the most important domestic policy reform has been the elimination of price supports to producers of basic crops. The producer price of corn was supported through government procurement by CONASUPO (the National Basic Foods Company). The 1991 nominal rate of protection to corn was 77percent and the producer subsidy equivalent (PSE) amounted to \$92 per tonne for white corn and \$71 per tonne for yellow corn, compared to \$28 in the US and \$21 in Canada. Consumer prices were also subsidized, but mainly for urban consumers through access to CONASUPO stores. In these government-run stores, consumers could purchase cheaper corn that the government had acquired from producers at inflated prices. However, few farmers live close enough to such stores so as to sell corn at the high support price and then buy their consumption needs at the low subsidized prices.²³

²³ De Janvry, Sadoulet and de Anda (1995).

CONASUPO's role in the corn market was substantially diminished in 1995 as a result of the Mexican peso crisis. The peso devaluation in 1995 allowed the Zedillo government to transform CONASUPO into a buyer of last resort and eliminate price supports to corn farmers. However, because of the drop in corn prices in 1996, the government of Mexico reinstated an intermediate scheme of price fixing whereby prices were fixed on a regional basis at a level between the guaranteed price and the international price. This scheme was abolished in 1999.²⁴

Some Mexican corn producers currently receive a fixed subsidy per ton of marketable surplus under the Marketing Support Program. In order to participate in this program, producers must have a marketable surplus. Relatively few farmers (around 10 percent) fit this description (Zahaniser et al. 2004). PROCAMPO was initiated in the winter of 1993/94, a few months before the beginning of NAFTA. The program was designed to supplement farmers' income and moved support in the direction of income transfers. Payments were based on area under cultivation. Its main purpose was to help farmers facing stiff competition from US and Canadian farmers make a transition to more competitive crops. It is intended to last until 2008 when full trade liberalization under NAFTA will be complete.

There are several other reforms that took place during the 1990s not specifically aimed at corn farmers but that would nevertheless impact them. The first is the Alliance for the Countryside (*Alianza para el Campo*). It includes PROCAMPO as well as other programs. One of the most important programs is PRODUCE which is an extension program designed to increased productivity via improved technology. Liberalization of the agricultural sector also entailed the elimination of subsidized inputs such as seeds fertilizer and credit. Finally, the Salinas government amended the constitution in 1991 to liberalize property rights in the *ejidal* sector. Until this time, peasants that benefited from land redistribution, *ejidatarios*, were by law not allowed to associate, rent or sell their land. The constitutional amendment abolished this provision and is expected to develop rural land markets by allowing farmers to participate in private credit markets and by promoting direct investment.

²⁴ CONASUPO also subsidized tortilla processors and maize millers by selling to these processors the maize purchased from farmers at a price that would allow the processors a "reasonable" profit.

Based on the preceding discussion, it should now be clear that when we refer to NAFTA, we are not simply referring to a removal of tariffs on imported corn. NAFTA was much broader than that. In what follows, we use NAFTA to represent domestic policy changes (“my policies”) that impact the Mexican producer price of corn.

4.2 What Determines the Mexican Producer Price of Corn: My Policies or Yours?

There is no doubt that NAFTA is having an impact on US-Mexico corn trade. Figure 5 confirms the findings of others that US corn exports to Mexico (the US is the only country that exports significant amounts of corn to Mexico) have increased dramatically since the signing of NAFTA.²⁵ Moreover, prior to NAFTA, the US exported virtually no white corn – the type of corn typically grown by Mexican corn farmers - to Mexico. However, as Figure 5 shows, the amounts of both yellow and white corn exported from the US to Mexico increased substantially after the signing of NAFTA.²⁶ As a share of Mexican corn production, US imports increased from an average of 8.4 percent of total production in the eight years leading up to NAFTA to an average of 32.6 percent of total production in the eight years following NAFTA.

Figure 6 shows that the average real price paid to producers of corn in Mexico dropped significantly between the period 1986 and 2002. Part of the drop in Mexican producer prices has to do with the drop in the world price of corn; the Mexican producer price follows fairly closely the border price. In Figure 6 we plot the annual average Mexican producer price in real 1994 pesos against the annual average border price also reported in real 1994 pesos. The border price was obtained from the OECD’s Producer Support Estimate database and reflects the cost of importing US corn at the border including freight charges to the border but not within Mexico. US dollars are converted to pesos using an annual average of the official exchange rate. Both series are converted to 1994 pesos using the national consumer price index.

²⁵ See, for example Zahniser and Coyle (2004).

²⁶ The distinction between yellow corn and white corn is an important one. Mexican corn farmers primarily grow white corn which is used to make food products. Yellow corn is typically used to feed animals. However, there is some substitutability between yellow and white corn. Food-grade yellow corn is used to make corn flakes, chips, beer and other foods and white corn can be used as animal feed (Zahniser and Coyle 2004).

There are two important pieces of evidence to take away from Figure 6. First, while the two price series moved closely together throughout the 1990s, 1996 was an exception. In 1996, the two series diverge as US prices increase and Mexican prices drop. Indeed in 1996, Mexican producers were actually taxed, and were receiving only 88 percent of the US price for their product. Thereafter, the two series continue to move closely together. Second, prior to NAFTA, the gap between the Mexican price and the US price is significantly greater than the gap post-NAFTA. Indeed, the average nominal protection coefficient (ratio of the Mexican producer price to the border price) for the period 1986-1995 is 1.61 while the average nominal protection coefficient for the period 1996-2002 is 1.17.²⁷

We test the patterns suggested by Figure 6 more formally in a regression framework and report these results in Tables 5 and 6. For US prices, we use the same price series shown in Figure 6. For Mexican producer prices, we now use a separate price series for each of Mexico's 32 states. Our time series covers only 1991-2000 since these are the years for which we have price data at the state level. Also in Tables 5 and 6, we explore the possibility that states further from the border where the poorest corn farmers live are less affected by changes in world prices and NAFTA. Following Nicita (2004), we assign states to four groups depending on their distance from the US border.²⁸

Table 5 presents the results of regressions of the real Mexican producer price for each state on real border prices. To eliminate the common time trend, we first difference both price series. In column (1) we report the results of the simple correlation between Mexican and US prices. Not surprisingly, the correlation is positive. In column (2) we test whether this relationship has changed significantly as a result of NAFTA. The weak and negative sign on the interaction term is counterintuitive and suggests that the relationship between Mexican and US prices weakened after NAFTA. However, in column (3), we introduce a control for the sudden shift in policy in 1996 and find that the coefficients on the NAFTA terms are now insignificantly different from zero. We

²⁷ The results are even more pronounced if we do not include 1995 in the pre-NAFTA average.

²⁸ Border states are Baja California, Sonora, Chihuahua, Coahuila, Nuevo Leon, and Tamaulipas. Northern states are Sinaloa, Nayarit, Zacatecas, Aguascalientes, San Luis Potosi, and Durango. Central states are Jalisco, Colima, Michoacan, Guanajuato, Queretaro, Estado de Mexico, Hidalgo, Distrito Federal, Tlaxcala, Morelos, Puebla, and Veracruz. Southern states are Guerrero, Oaxaca, Chiapas, Tabasco, Campeche, Yucatan and Quintana Roo.

interpret this as evidence that, except in 1996, Mexican and US prices moved closely together both before and after NAFTA. In column (4), we restrict the sample by dropping 1996 and test for the possibility that Mexican prices might follow more closely the world price in states closer to the border – we find no evidence of this.

In Table 6, we test whether a relaxation of tariffs on imported corn reduced the wedge between the Mexican producer price of corn and the border price. In column (1), we do this by regressing the ratio of the Mexican price to the US price on a NAFTA dummy. The results indicate that prior to NAFTA, Mexican prices were 1.62 times the US price and that post NAFTA Mexican prices were only 1.18 times the US price. These numbers are consistent with the simple calculations based on the annual data used to plot Figure 6. In column (2) we test whether this differential is any smaller for states closer to the border and find no evidence of this. In column (3) we test whether the differential changed more (less) in states close (far) from the border. Since the only term of any significance is the NAFTA dummy, we conclude that this is not the case.²⁹

These results suggest that while the Mexican producer price has always moved in tandem with the world price, NAFTA squeezed the differential between Mexican producer prices and border prices. How much higher would the border price be if the US were not subsidizing corn? Unfortunately, there is no consensus on this issue, as commodity prices are notoriously difficult to predict. However, though the estimates vary depending on the methodology, the bottom line seems to be that the magnitude of the price difference would actually be quite small. Wise (2004) summarizes these results and reports that the largest estimate of 2.9 percent comes from a study by IFPRI. The

²⁹ Since these results are at odds with a recent publication by the World Bank (Fiess and Lederman, 2004), we note a few differences between our study and the Bank study. The Bank study performs a co-integration analysis using monthly price data at the national level. They report that the results are unchanged if they use annual data. Similar to us, they find a high degree of co-movement between US prices and Mexican prices. However, unlike us, they report that the differential between Mexican and US prices is the same pre and post NAFTA. They also plot their prices series but a comparison between our Figure 6 and their Figure 4 is difficult because they take logs of nominal prices whereas we plot levels of real prices. The most confusing thing about the Bank study is the fact that they report that their results do not hold unless they include a dummy variable for the periods 1995-1997. They justify this on the grounds that this was a period of severe drought during which Mexico imported record amounts of US corn. There are at least two problems with this. First, while it is true that Mexico imported record amounts of corn in 1996, this is not the case for 1995 nor is it the case for 1997 (see Figure 1). Therefore, it is unclear why the dummy should take a value of one in 1995 and 1997. Second, the dummy variable captures half the post-NAFTA period and so to include it but not incorporate it in the constant term that the authors report to be the price differential seems misleading.

smallest estimate (-3.0 percent) is from a study by APAC and implies that removing US subsidies would actually raise producer prices! In 2000, a 3 percent increase in the producer price of corn would increase the poorest farmers' monthly income by at most 6 pesos (USD 0.63).³⁰

In summary, the sharp drop in Mexican producer prices over the period 1990-2000 corresponds almost exactly to NAFTA's effective date. Though it is possible that Mexican producer prices would be higher if the US did not subsidize corn, the magnitude of this effect seems small both in comparison with the effect of trade liberalization and in absolute terms. In addition, since there was no dramatic change in US farm policy over this period, Mexican prices would have been higher throughout the entire period. Thus, it seems unlikely that US corn subsidies are driving poverty in Mexico unless one takes the stand that US corn farmers as an interest group were largely responsible for NAFTA.

4.3 How Did the Drop in Mexican Producer Prices Affect Poor Corn Farmers?

In this section we turn to analyzing the distributional consequences of the drop in producer prices that we documented in section 4.2. We can think of this analysis as answering two distinct questions. First, the focus of this paper – who in poor countries bears the brunt of rich country support to agriculture? And second, the focus of this volume – how does trade liberalization affect the poor?

Data

Our data on corn farmers comes from the agricultural supplement of the *Encuesta Nacional de Empleo* (ENE) collected by the *Instituto Nacional de Estadística, Geografía e Informática* (INEGI) in Mexico. This survey covers 453,503 individuals in rural areas,

³⁰ Finally, we consider the possibility that the steep decline in the real producer price might be partially due to the large devaluation of the Mexican peso in 1995. The direct effect of the devaluation would have been to offset the decline in tariffs on imported corn thus protecting Mexican corn farmers. However, there are two indirect effects that must be considered. First, there is the inflation that was a byproduct of the devaluation. Second is the strain on the government budget. We note that the average rate of inflation over the period 1986-1994 was 43 percent while the average rate of inflation from 1995-2000 was only 22 percent. Therefore, it is difficult to argue that the inflation was the root cause of farmers' problems. Additionally, the government has continued to support corn farmers albeit not directly. These programs are expensive and have managed to keep farmers' real income (including transfers) from falling dramatically over the period 1990-2000. Based on this evidence, we conclude that the change in farmers' income from corn farming is directly tied to the changes in the price of corn at least partially brought on by NAFTA.

is nationally representative, and was undertaken in 1991, 1993, 1995, 1996, 1997, 1998, 1999 and 2000. The agricultural supplement is rich in detail about crop production, land quality and size, wages, hired labor, dwelling characteristics, and total farm output-- thus it provides a detailed description of the production side of corn farming-- as well as containing demographic, employment and income information from the broader employment survey. This dataset has rarely been exploited and this study is the first, to our knowledge, to use the ENE agricultural component to analyze welfare effects on Mexico's rural sector. The dataset is not a panel, as each subject is only interviewed once but is a repeated cross-section. INEGI did not, however, alter its sampling procedures over the years in question so it is relatively safe to conclude that changes we see among sectors is due to compositional changes in the population, as opposed to compositional changes in the sample

The ENE data, however, only includes income from the respondents' primary occupation and does not include consumption data. To allow a broader analysis of welfare, we complement the ENE data with data from the *Encuesta Nacional de Ingresos y Gastos de los Hogares* (ENIGH). This survey covers 21,117 rural households and covers the years 1992, 1994, 1996, 1998 and 2000. These data are also nationally representative repeated cross sections and do not follow the same households over time.³¹ At the household level, the survey asks for a measure of total household income and income from transfers including remittances (domestic and international), and subsidies from PROCAMPO and other government programs. At the individual level, the survey asks each member of the household how much he/she earns and whether it is derived from wages, the individuals' own business enterprise, or other sources such as rental income. We aggregate individual incomes by household to come up with the following breakdown of the household's total income: profit income, work or labor income, income from remittances, income from transfers and other. In addition, the survey asks whether a

³¹ For the years 1992-2000, the conceptual framework of the survey is the same. Therefore, we are able to compare results across years. The survey is a stratified sample according to urban and rural location and sampling is done to ensure that households are representative of geographic clusters with the probability of being included proportional to cluster size. However, a comparison of national accounts data and the ENIGH survey data suggests that up to 60 percent of income goes unreported in the ENIGH survey. However, Damian (2000) and others report that this problem derives primarily from the difficulty of including the very wealthy Mexicans in the survey. Since our analysis focuses largely on the rural poor, we believe that our results are not significantly affected by this problem (Salas 2003).

household's primary or secondary source of income is corn farming. The survey also has a detailed consumption module, which recounts household expenditure on food, including corn and corn products, education, health, housing, clothing, etc.

Table 7 presents means of socio-economic characteristics of the rural population from ENE for the entire sample period. All means were computed adjusting for population weights. For purposes of comparing corn farmers with the rest of the rural population, we have divided our summary statistics into four panels. Panel A reports statistics for all rural dwellers. Panel B reports statistics for all rural dwellers involved in agriculture. These are identified as those respondents who report that the industry of their primary occupation is agriculture and includes farm laborers as well as those who own or rent the land. Panel C reports statistics for farmers where farmer is defined as someone who takes part in agricultural activities and owns, occupies, or rents land (as opposed to agricultural laborer). Finally, Panel D reports statistics for a subset of the farmers in Panel C who report that their primary occupation is the cultivation of corn and beans. In each panel, we report mean monthly income in real 1994 pesos. Income is defined as total household income and the majority of respondents (97.5 percent) report that their income comes in the form of profits and family consumption. The measure of income in ENE does not include remittances or transfers. We also report mean age, years of schooling, hours worked and total usable land occupied by the respondent. To determine the relative importance of corn farming, we report the percent of respondents in each year who claim that their primary occupation is corn farming (Corn Occupation), that their primary crop for subsistence is corn (Corn Subsistence) and that their main crop for selling is corn (Corn Selling).

These data highlight several important facts. The share of the rural population that consider themselves farmers has fallen from 14 percent of the rural population in 1991 to 9 percent of the rural population in 2000. Corn farmers make up 20 percent of the rural population in 1991 and only 10 percent of the rural population in 2000. Among farmers, a majority are corn farmers – though this dropped from 62 percent in 1991 to 54 percent in 2000. Three quarters of all farmers say they grow corn as their primary crop for subsistence. However, very few farmers (between 12 percent and 22 percent) say that corn is their primary crop for selling.

Thus, most farmers are corn farmers and this has not changed very much over the past ten years. This is important because it implies that there has not been a significant amount of diversification into other farming activities away from corn farming. Corn farmers have on average more land than the average rural dweller and are poorer than other farmers and than the rest of the population. The *average* real monthly income from corn farming in 2000 was only 206 pesos or \$21.79 or \$261.48 per year.³² Finally, corn farmers also have less schooling and work longer hours than the rest of the rural population.

Table 8 presents means of real household variables for families in which at least one individual identifies his or her primary occupation as the cultivation of corn and beans. In the top panel of Table 9, we report real monthly household expenditure on corn, expenditure on corn as a share of total food expenditure, expenditure on corn as a share of total expenditure and the quantity of corn purchased. Corn includes corn tortillas, grain, flour, *masa*, and starch and corn consumption includes corn purchases, corn produced for household consumption and in-kind payments and gifts of corn. There are two important aspects of these data worth mentioning: First, we are not looking only at expenditure on corn grain but expenditure on corn grain and all derivative products, allowing us to capture the impact of imported grain on all of these products. In particular, our expenditure data includes corn tortillas whose price went up sharply during the 1990s for reasons unrelated to NAFTA. We include tortillas on the grounds that prices would have risen even more had the price of corn grain not fallen. Second, both our income and expenditure data includes the value of home consumption, in-kind payments, and gifts. Therefore, the change in consumption expenditure can be viewed as an upper bound on the increase in real income associated with the drop in the price of corn.

In the bottom panel of Table 8, we report total real monthly household income as well as real monthly income derived from work (labor income), profits, government transfers and remittances. Since the income reported in Table 8 is household income and the income in Table 7 is income derived from the respondents' primary occupation or individual income, the two numbers are not directly comparable. However, the income

³² The average annual exchange rates (Mexican pesos per dollar) beginning in 1990 are: 2.84, 3.02, 3.1, 3.12, 3.39, 6.42, 7.6, 7.92, 9.15, 9.55, and 9.45.

data from the national employment survey (ENE) derives primarily from profits and home consumption and would fall under “income from profits” at the household level. Therefore, by comparing the national employment survey income data with the ENIGH household survey income data we can get a sense both for how important profits from corn farming are and also how important supplementary sources of income are to corn farming families. For example, in 1996, the profit share of income for corn farming families was roughly 327 pesos per month. According to the national employment survey data, the average real income earned from corn farming by the corn farmer was roughly 268 pesos per month. This is equal to 82 percent of the profit share of income reported in the household data or 32 percent of the average corn farming families’ total real monthly income. Thus, profits from corn farming are on average the most important source of income for families of corn farmers but work income and income from transfers are also important at 23 percent and 19 percent of total income respectively.

The means in Table 8 reveal that – for the *average* corn-farming family – aggregate corn consumption and aggregate income have not changed remarkably between 1992 and 2000. Real monthly expenditure on corn fluctuates between 77 and 55 pesos per month. The average family spends around 19 percent of its food budget on corn products and around 10 percent of its total budget on corn products. The average family’s real monthly income was 907 pesos (USD 292) in 1992 and 856 pesos (USD 90.58) in 2000. Note that, to the extent that these families purchase imported products, the peso values understate the drop in real income.

While expenditure on corn did not change significantly following NAFTA for the average corn-farming family, there has been a marked change in the composition of income. In 1992, the profit share of income was roughly 53 percent and this fell to around 39 percent in 2000. The work share of income also fell from around 24 percent in 1992 to around 20 percent in 2000. The drop in these two sources of income was largely offset by an increase in income from transfers (11 percent in 1992 and 23 percent in 2000).

In the next two sections, we examine the data from the national employment surveys (ENE) and the household surveys (ENIGH) on corn farmers and families with corn farmers by standard of living, as measured by land holdings. Our primary goal is to

determine how the drop in the price of corn has impacted the poorest corn farmers and the poorest corn farming families in Mexico.

Results from the National Employment Surveys (ENE)

Here we analyze in more detail the sub-group of the rural population who identify themselves as corn farmers. Recall that these are individuals who own, occupy, or rent land (as opposed to agricultural laborers), and who claim that their primary occupation is the “cultivation of maize and beans.” We recognize that farm laborers are an important group of rural dwellers whose wages are likely to be affected by changes in the price of corn. We do not attempt to consider the welfare of these individuals here. Rather, our goal is to determine how the drop in the price of corn affected the poorest corn farmers in Mexico. To do this, we divide corn farmers into three groups – small, medium and large - depending upon the size of the farmers land. We then determine whether a majority of the poorest corn farmers, those with the smallest land holdings, are net buyers or net sellers of corn.

Table 9 reports corn farmer characteristics by total land holding across time.³³ The mean landholding of the smallest corn farmers (those with less than 5 hectares of land) is roughly 2 hectares. This corresponds to the average land held by the poorest corn farmers identified by De Janvry, Sadoulet and de Anda (1995) as “non-participants in the market” and by Levy and Van Wijnbergen (1995) as “subsistence” who primarily farm rain-fed land. The mean land holding of the medium-sized corn farmers (those with between 5 and 15 hectares of land) is roughly 8.5 hectares. The mean land holding of the largest corn farmers (those with more than 15 hectares of land) is roughly 35 hectares. For small, medium and large corn farmers we report means of real income, age, years of schooling, hours worked and land holding over time. In addition, we report the percent of the population who say that their main crop for subsistence is corn (Corn Subsistence), the percent of the population who say that their main crop for selling is corn (Corn Main

³³ The advantages of splitting the sample based on landholding are that we do not have to worry about measurement issues associated with income and that we can directly compare our results to others who also classify corn farmers by landholding. In Appendix Table 2, we report income based, monthly per capita measures of poverty. By Mexican standards, only our average small corn farmer is classified as extremely poor. The medium corn farmers earn enough monthly income from corn farming to place them above both

Crop for Selling Selling) and the percent of the population who say that they do not produce a crop to sell in the market (Do Not Produce to Sell).³⁴

For the poorest farmers (those with less than 5 hectares of land), we report statistics for two additional variables. We do this because we are concerned that the poorest farmers (often called subsistence farmers) may occasionally sell corn but nevertheless report that they do not produce corn with the intent of selling. To determine the extent to which this takes place, we first report the percentage of poor farmers who answer the question “which of your subsistence crops do you sell?” with corn. We label this “Occasionally Sell Corn”. Next we determine the percentage of respondents who report that they never sell corn as the fraction of the poorest who report that they do not produce to sell but nevertheless answer that they sometimes sell the corn they grow for subsistence. We label this variable “Never Sell Corn”. There is no need to do this for the medium and large corn farmers because we already know that a majority of these farmers do sell corn in the market.

A majority of the poor report that they do not produce to sell. In 1991, 67 percent of the small corn farmers reported that they did not produce to sell in the market. This figure peaks at 77 percent in 1993 and falls to 63 percent in 2000. An overwhelming majority of these same farmers, 89 percent in 1991 and 92 percent in 2000, do say that corn is their primary crop for subsistence. Once we allow for the possibility that some of these farmers may sell corn on occasion, the percentages fall and we are left with a somewhat stronger conclusion. The majority of the poor report that they never sell corn in all of the 8 years for which we have data. For example in 1991 56 percent of the poorest farmers report that they never produce to sell and in 2000 57 percent report that they never produce to sell.

By contrast, only around 33 percent of the medium-sized farmers and 16 percent of the large farmers say that they do not produce to sell. Therefore, the drop in the price of corn associated with NAFTA does not directly affect the income of the majority of the poorest corn farmers while it negatively impacts the income of a majority of the medium-

the extreme poverty line and the moderate or asset based poverty line. However, in 2000, by international standards, the medium corn farmers would be considered moderately poor.

and large-scale corn farmers. Though the employment survey does not ask about expenditure, those farmers who report that they do not sell are most certainly net buyers of corn. It is almost impossible to be completely self-sufficient because of the vagaries of the weather. Thus, among the poorest corn farmers, the majority are net buyers of corn and have thus *benefited* from any reduction in the price of corn associated with NAFTA. The opposite is true for the medium- and large-scale corn farmers.

Though not shown in the tables, we also analyzed the summary statistics by splitting the samples in panels A, B, and C into those who sell and those who do not sell. In all three cases, the corn farmers who report that they do not produce to sell are poorer, older, less well educated, and have less land than the farmers who do produce to sell. Additionally, the corn farmers who report that they do not produce to sell also report that the majority of their income comes in the form of family consumption while those who do produce to sell report that the majority of their income comes in the form of profits. With only one exception, all groups and sub-groups of corn farmers saw their real income decline substantially between 1991 and 2000. Only large corn farmers experienced a substantial increase in their income between 1995 and 2000. If we split large farmers into those who produce to sell and those who do not produce to sell, we find that the larger corn farmers who do not produce to sell actually experienced a decline in their real income over the period 1991 to 2000. However, the increase in the incomes of those large farmers who do produce to sell is even more dramatic (684 pesos per month to 1162 pesos per month) once we remove the large corn farmers who do not produce to sell.

In Table 11, we check whether there has been a significant change in the characteristics and real income of corn farmers pre- and post-NAFTA. In terms of both magnitude and statistical significance, the most striking changes are the reduction in the real income of small farmers and the increase in the real income of large farmers. Between 1991 and 2000, small farmers real monthly income dropped by roughly 285 pesos while large farmers' real income increased by around 100 pesos. Between 1995 and 2000, small farmers real income dropped by roughly 93 pesos while large farmers' real monthly income increased by around 300 pesos.

³⁴ To keep the tables clear and manageable, we leave out the percent of the population who report that they do not sell any of their subsistence crop. An analysis of this variable leads to the same conclusion that the majority of the poor report that they do not sell any of their subsistence crop.

The drop in the real income of the small farmers can be explained by the reduction in the price of corn. Though the majority of these farmers do not participate in the market, they do report that their most important source of income from their primary occupation is the value of home consumption. Thus, even for those farmers who do not participate in the market the imputed value of real income will have fallen.

The increase in the income of the large farmers is somewhat more puzzling. However, this could be explained by a number of factors. For example, it is consistent with Levy and Van Wijnbergen's (1995) argument that irrigated farmers would experience an increase in net income because the gain they experience as a result of the drop in rural wages outweighs the loss they experience as a result of the reduction in the price of corn. We hope to explore in more detail the reasons for the gain in large farmers' real income in future work.

In summary, the majority of the poorest corn farmers did not sell corn in the market prior to NAFTA. Therefore, their income will not have been directly affected by the forces of globalization associated with NAFTA and the devaluation of the peso. By contrast, a majority of the medium and large corn farmers did sell corn in the market prior to NAFTA and continued to do so after the implementation of NAFTA. Thus, we conclude that the medium-sized corn farmers experienced a sharp decline in real income as a result of NAFTA. The income of the largest corn farmers has increased. Without additional information, it is not possible to attribute the increase in the incomes of the large corn farmers to globalization.

Results from the Household Surveys (ENIGH)

We turn now to the families of those individuals who identify their primary occupation as the cultivation of corn and beans. Specifically, we examine household expenditure on corn products and the sources of total household income. Ideally, we would like to have this information for the same individuals interviewed in the employment survey. This would allow us to understand whether the poorest families who say they do not sell any corn rely on other sources of income that might be indirectly affected by the price of corn such as wage income derived from working on other peoples' corn farms. Unfortunately, the surveys were not conducted in this fashion.

Therefore, we split our sample into three groups based on income from profits on the grounds that income from profits are very closely correlated with the size of the land holding. Thus, we take the families in the bottom tercile of the distribution of income from profits as the “representative families” of the corn farmers with less than 5 hectares of land. Similarly, those in the middle of the distribution represent the families of the medium-sized corn farmers and those in the top third of the distribution represent the families of the largest corn farmers (those with more than 15 ha. of land).

Panel A of Table 12 reveals that for the average low-income corn farming family real monthly expenditure on corn decreased by around 20 pesos per month over the period 1994-2000. This amounts to around USD 2 per month or USD 24 per year for the poorest corn farming families. We noted in the discussion of these data that this would be an upper bound on the benefits to the poorest corn farming families as a result of the drop in the price of corn. This is because these families are so poor that they often cannot afford to buy corn and so will go without and because the consumption figures include the value of home consumption. For the poorest corn farming families, the share of corn in food expenditure stayed roughly constant at around 25 percent and the share of corn expenditure in total expenditure stayed roughly constant at around 15 percent.

On the income side, the big changes for the poorest families over the period are the drop in the profit share of income and the increase in transfers. Monthly income from profits was around 130 pesos higher in 1992 and 1994 than it was in 2000. On the other hand, transfer income increased threefold over this same period. The share of income derived from corn farming drops only slightly. Since expenditure on corn changed only marginally and since work income was hardly affected, we conclude that the welfare of those families who do not sell corn in the market – the majority of the poorest corn farmers - has been largely unaffected by the drop in the price of corn. Moreover, these families have benefited from the income support programs associated with NAFTA.

Panel B of Table 12 reveals a different story; the drop in the price of corn negatively impacted the majority of middle-income families. This is because the majority of these farmers do sell corn in the market. Total monthly expenditure on corn for these farmers has barely changed over time. Like the poorest corn farmers, work income has also not changed much over time. The profit share of income for the middle-income corn

farmers fell by 276 pesos between 1992 and 2000 and by 177 pesos between 1994 and 2000. This represents a reduction in real income of almost 50 percent. This was almost entirely offset by the increase in government transfers (128 pesos) and the increase in remittances (33 pesos).

Panel C of Table 12 demonstrates that both profit income and income from transfers increased substantially over this same time period. Other sources of income were largely unaffected. Income from profits for the high-income corn farmers increased by 190 pesos between 1992 and 2000 and by 208 pesos between 1994 and 2000. This amounts to an increase in real income of roughly 33 percent. Thus, the majority of the high income families benefited from changes in the Mexican corn market.

There are several other interesting trends that stand out in Table 12. First, households from all income groups witnessed an increase in income associated with government transfers from programs like PROGRESA and PROCAMPO. The largest percentage increase was given to the poorest corn farmer families whose income from transfers increased by 200 percent going from 44 pesos a month to 122 pesos a month between 1992 and 2000. Though transfers to the middle- and upper-income corn farmer families increased by less in percentage terms (100 percent), in absolute terms these families receive substantially more than the poorest corn farmer families in transfer payments from the government. For example, in 2000, the average middle-income family received a monthly payment of 215 pesos while the average upper income family received a monthly payment of almost 300 pesos roughly three times what the poor household received.

Second, the increase in transfer payments may explain part of the "mysterious" increase in corn production even though the real price of corn has fallen dramatically. Levy and Van Wijnbergen (1995) discuss this possibility in great detail. Liberalization of the corn sector under NAFTA creates an incentive problem. Because many corn farmers will be hurt, the government has an incentive to compensate these farmers for their losses. Levy and Van Wijnbergen estimate that the efficiency gains associated with NAFTA would be substantial and that this revenue could be used to compensate the losers. However, compensating farmers pro rata to their corn production will create an incentive to continue to grow corn even in the face of falling market prices.

4.4 Discussion

While thought provoking, our analysis suffers from two important shortcomings. First, we consider only the first-order effects of price changes on income and consumption expenditure while ignoring both the partial equilibrium effects of food price changes on quantities demanded and supplied and the general equilibrium effects of the price changes on employment patterns, wages, the price of other factors and technological innovation. Thus, our analysis is best thought of as a good approximation to what happened in the short run (see Panagariya 2000, Barrett 1996).

We focus here on short-run impacts of “globalization” for two related reasons. First, using short-run changes seems to be most appropriate for studying the impact of price changes on the poor, who, as Barrett and Dorosh (1996) say, are “likely to be teetering on the brink of survival” and less able to take advantage of supply-side effects of price changes. And second, our primary goal is to understand whether globalization has affected the poorest corn farmers. In future work, we will incorporate the general equilibrium effects of changes in the price of corn. In particular, an important group that we have not considered here are farm workers. Though not technically corn farmers, these people are likely to be among the poorest of the rural population and their livelihoods significantly impacted by changes in the price of corn.

We are also – in part - limited by our data. Since our datasets are not panels but are repeated cross-sections, there is a concern that our results might suffer from selection bias. The composition of small, medium and large corn farmers could be changing over time, as could the structure of the larger corn-farming sector. This means that we could be picking up a compositional effect rather than the effect of globalization. It is clear from Table 7 that the absolute number of families in which at least one person reports that his primary occupation is corn farming has fallen over the past decade. Therefore, it is possible that some poor corn farmers left corn farming for other, better paying jobs and that those particular corn farmers could have been the most able, educated ones. Thus, the negative impact on corn farmers that we observe in the cross sectional data over time could be partially a result of the corn farmers with the best outside opportunities (something which likely correlates well with present income) leaving corn farming. Any

complete statement about changes in the overall welfare of corn farmers would need to take selection into account, and to correct for it when studying the impact of globalization on poor corn farmers. It is also independently interesting to study which corn farmers were able to adjust and leave corn farming when the price of corn decreased, and which were not able to leave, but adjusted in other ways, possibly by increasing their production of corn.

However, our conclusion that the majority of the poorest corn farmers and their families have not been hurt by globalization is likely to hold regardless of the shortcomings of our analysis. This is because these people were so poor to begin with that it is hard to imagine them worse off as a result of globalization. They were not selling corn in the market and they did not rely heavily on income from work. Hence, for these people there is really only upside potential.

5 Conclusion

This paper documents the historical impacts of OECD agricultural policies on developing countries. We first provide evidence that the majority of poor countries are net importers of both cereals and food but net exporters of agricultural products as a whole. This has been true throughout the post-colonial era. Even middle-income countries that export food products are net importers of cereals, particularly in the 1990s. Thus, to the extent that OECD support policies depress the price of cereals and food, these programs benefit consumers in poor countries. Of course, even if a country is a net importer, competition from subsidized imports will hurt the net sellers of these products within the importing countries. However, there is a growing body of evidence – consistent with our evidence from Mexico – indicating that the poorest individuals in the poorest countries are actually net buyers of cereals and food and therefore benefit from lower food prices.³⁵

Our econometric results are consistent with this evidence and suggest that in many food-importing developing countries, OECD support policies are not correlated with the poverty rate or with income, even after controlling for domestic policies such as openness to trade. Consequently, the results suggest that OECD agricultural policies do

³⁵ See for example, Levinsohn and McMillan's piece on Ethiopia in this volume.

not have a uniform impact on developing country incomes; net food importing countries are likely to gain, while food exporters are likely to be hurt.

In the high-profile case of Mexico, we find that NAFTA reduced the wedge between the real producer price and the border price, making corn production less profitable. We also find that the poorest corn farmers are net food buyers, since they have little land per person, and so are forced to earn cash income in other ways in order to buy food. Therefore, the reduction in corn prices was unambiguously good for the majority of the poorest corn farmers. However, we also find that middle-income corn farmers have been hit hard as their real income from corn farming fell by more than fifty percent while the average income of the largest corn farmers increased by almost forty percent. Though the price of corn is no longer directly supported by the Mexican government, transfer payments to corn farmers at all levels of income increased substantially between 1991 and 2000. Because these payments are often tied to amount of land cultivated with corn, their increase may explain the “puzzle” of increasing corn production in the face of falling corn prices.

Our findings may be taken as a note of caution in the context of arguments for wholesale multilateral agricultural trade liberalization in industrial countries as a means of alleviating poverty in developing countries. The aggregate efficiency gains associated with trade liberalization, a topic not addressed in this paper, may mask negative impacts for many developing countries, particularly the poorest. Trade negotiators may need to consider means of protecting these countries from the negative effects of higher commodity prices, at least in the short run, and developing countries may find it advantageous to advocate for more far-reaching liberalization in the cotton, dairy, and sugar markets rather than in the markets for bulk grain commodities that they import.

Source: World Development Indicators (trade share and CPI), Penn World Tables (income), and World Bank PovertyNet (headcount), FAOSTAT and SourceOECD (OECDNPC).

Note: Cereal and food importers defined as countries that had negative values of net exports of cereals and food on average in 1970s.

The average Southern Oscillation Index anomaly has an average value of -0.58 (std. dev. 1.18).

Constant	-63.912 (7.38)**	-95.931 (8.86)**	-95.931 (8.82)**	-76.424 (3.39)**
Observations	224	224	224	192
R-squared	0.08	0.11	0.14	0.16

Notes: Robust t-statistics in parentheses. Mexican producer prices are annual by state and were obtained from SAGARPA. They were deflated to real 1994 prices using the national CPI. United States prices were obtained from the OECD Producer Support Estimate database and are the c.i.f. import price of corn not including transport or processing costs from the Mexican border to Mexican consumers. US prices were converted to Mexican pesos using the annual average official exchange rate. Mexican and US prices are in first differences to eliminate the common time trend. NAFTA is a dummy equal to one for the years 1996-2000. Results are robust to defining the NAFTA dummy equal to one also in 1995. The omitted category is Border states. These are: Baja California, Sonora, Chihuahua, Coahuila, Nuevo Leon, and Tamaulipas. Northern states are: Sinaloa, Nayarit, Zacatecas, Aguascalientes, San Luis Potosi, and Durango. Central states are: Jalisco, Colima, Michoacan, Guanajuato, Queretaro, Estado de Mexico, Hidalgo, Distrito Federal, Tlaxcala, Morelos, Puebla, and Veracruz. Southern states are: Guerrero, Oaxaca, Chiapas, Tabasco, Campeche, Yucatan and Quintana Roo.

Notes: Farmer is defined as someone who takes part in agricultural activities and owns, occupies, or rents land (as opposed to agricultural laborer). Corn farmer is defined as a farmer who identifies his primary occupation as the cultivation of maize and beans. Corn subsistence is the percent of farmers who respond that their primary crop for subsistence is maize and beans. Corn selling is the percent of farmers who respond that their main crop for selling is corn. Source: ENE 1991-2000. Medians are not reported because they are virtually identical to means.

Notes: Farmer is defined as someone who takes part in agricultural activities and owns, occupies, or rents land (as opposed to agricultural laborer). Corn farmer is a farmer who identifies his primary occupation as the cultivation of maize and beans. "Corn Subsistence" is the percent of respondents who answer that their main crop for subsistence is corn. "Corn Main Crop for Selling" Selling" is the percent of respondents who answer the question "what is your main crop for selling?" as corn. "Do Not Produce to Sell" is the percent of respondents who answer the question "what is your main crop for selling?" as "I don't produce to sell." Occasionally Sell is the percentage of respondents who answer the question "how much of your subsistence crop do you sell?" with corn. Never Sell Corn is the percentage of respondents who answer they do not produce to sell when asked "what is your main crop for selling?" but who answer "which of your subsistence crops do you sell?" with corn. Medians are not reported because they are virtually identical to means. Source: ENE 1991-2000.

Notes: Consumption figures include corn purchases, corn produced for household's consumption, and in-kind payments and gifts of corn.

Cornfarmer is defined as someone who identifies his/her primary occupation as the cultivation of corn and beans. All means computed using population weights. The last four columns report the change in mean between 1992 and 2000 and then between 1994 and 2000. The column to the right of the change in mean reports the significance of a t-test with *** 99%, **95% and *90%. Source: ENIGH

Table A1: Description of variables and data sources

<i>Variable name</i>	<i>Source</i>	<i>Description</i>
Headcount poverty rate	World Bank Poverty Net	Constant \$1985 US Dollar; fraction of population with income less than \$1 per day
Log average income per capita	Penn World Tables 6.1	Constant \$1985 US Dollar, real GDP per capita
SOI anomaly	National Oceanic and Atmospheric Administration. Available: ftp://ftp.ncep.noaa.gov/pub/cpc/wd52dg/data/indices/soi	Southern Oscillation Index anomaly
OECDPOLICY	Source OECD Agriculture support estimates, available: http://oecdpublications.gfi-nb.com/cgi-bin/OECDBookShop.storefront/EN/product/512002093C3 USDA Economic Research Service Trade Issues data, available: http://usda.mannlib.cornell.edu/ FAOSTAT Agricultural production of primary crops, available: http://faostat.fao.org/faostat/collections?subset=agriculture	OECD average Nominal Protection Coefficient. Data included in regression as weighted average across commodities where weights are production shares for major commodity classes. These commodity classes are: wheat, maize, rice, other grains, oilseeds, sugar, milk, beef, sheepmeat, wool, pigmeat, poultry, eggs, coffee, cocoa, roots and tubers, fruits, vegetables (including melons). Data available from OECD for period 1987-2000, and USDA/ERS for period 1982-87. Data included in regression as weighted average across commodities where weights are production shares for major commodity classes listed above in 1970. Production share data from FAO.
Exports+Import/GDP	World Development Indicators	Exports and imports in constant 1985 US Dollars at market exchange rate. GDP is in \$1985 PPP
ln(1+inflation rate)	World Development Indicators	Log of rate of inflation plus one

Table A.2 Rural Poverty Lines for Mexico

Monthly Per Capita Poverty Lines (1994 Pesos)	1994	1996	1998	2000
Food Poverty/Extreme Poverty	43.29	87.61	117.52	139.78
Asset-poverty/Moderate Poverty	82.78	159.21	208.76	254.50
\$1/day poverty line	68.51	124.29	173.8	219.24
\$2/day poverty line	137.02	248.58	347.6	438.48

Notes: Source: ENIGH, ENE, World Bank (2004). Food Poverty is defined as the income required to purchase a food basket to satisfy minimum nutritional requirements. Asset poverty uses Engel coefficients to estimate the non-food component of income. Since our income data is in real 94 pesos and the poverty line estimates were originally in 2000 pesos, we used the general CPI to convert the poverty lines to real 94 pesos. Income from corn farming is only reported in the last three years because the available data for the earlier years does not correspond to the years of data available for household data.
